**Introduction**

The objective of this study was to compare the weight of roots and their stratification under 2-mow and 5-mow management of landscape lawns of *Lolium perenne*. The trials were carried out at Rousínov in the Czech Republic from 2007 to 2009. Nitrogen (N) was applied as fertilizers differing in forms and actions and at different levels of N rate (0, 50 and 100 kg ha⁻¹ y⁻¹). In the third year of the experiment the root weight of *Lolium perenne* was the highest. High doses of nitrogen (100 kg ha⁻¹ y⁻¹) increased the weight of the root biomass in the 0–20 mm layer.

**Methods**

A multi-factorial small-plot experiment was established in a randomized block design with three replications in September 2006 on the site of Rousínov, Czech Republic (phytogeographical region - termophyticum; soil class - loamy; altitude 229 m above sea level). Temperature and precipitation data at the experimental site are reported in Table 1. A cylindrical soil probe (50 mm in diameter) was used to take samples of grass turf monolith to a soil depth of 200 mm at the end of the vegetation season. The soil monolith was divided into the layers of 0–20 mm and 21–200 mm.

**Experimental factors:**
Factor 1 – year: a) 2007, b) 2008, c) 2009
Factor 2 – frequency of mowing: a) 5M - five per year, b) 2M - two per year
Factor 3 – the applied form of nitrogen in fertilizer:
   a) RN – N in a fast-soluble form, ratio of nutrients 15N-5P-20K + micro-elements ME;
   b) SN – with N stabilizer (nitrification inhibitor DMPP – Dimethylpyrazole phosphate), ratio of nutrients 14N-7P-17K+ME;
   c) DN – N in a long-term form (IBDU-condensate of urea), ratio of nutrients 16N-7P-15K+ME;
   d) C – control (without fertilizing)
Factor 4 – nitrogen dose: a) 0 kg ha⁻¹ y⁻¹; b) 50 kg ha⁻¹ y⁻¹; c) 100 kg ha⁻¹ y⁻¹ applied in two doses

**Results**

In the third year of the experiment the root weight of *Lolium perenne* was the highest. High doses of nitrogen (100 kg ha⁻¹ y⁻¹) increased the weight of the root biomass in the 0–20 mm layer.

**Conclusions**

This multifactorial study of the *Lolium perenne* root system within a three year period provides information about the root system’s response in two soil layers (0–20 mm and 21–200 mm) to different methods of extensive management of landscape lawns. Root biomass stagnated in the dry year 2008 and increased markedly in the wet year 2009. The only management factor which produced significant differences was nitrogen dosage.
